

This explanation helps answer the following question:

Which recorded characteristics can stay the same while the model still refuses, and what change would bring the model estimate below 12.0%?

Main takeaway: for this application, revolving-credit use of 78% together with two recent late payments is enough in the explanation's comparison to keep the model outcome as refusal. If those values are instead 61% and 0, the model estimate becomes 11.7%, which is below the bank's 12.0% refusal cutoff.

Assessment note: the model below is another representation of the same explanation content. Judge the information conveyed, not the visual design.

PART 1 - WHAT IS ENOUGH TO KEEP THE REFUSAL

Values sufficient to keep the refusal

Use of available revolving credit

78%

Recent late payments

2 in the last 12 months

PART 2 - WHAT SWITCHES THE RESULT TO APPROVAL

Hypothetical comparison

As submitted

18.4%

Model credit-risk estimate

Refused

Hypothetical comparison

11.7%

Model credit-risk estimate

Approved
