

This explanation helps answer the following question:

How does the model's average risk estimate change as these applicant characteristics increase?

Main takeaway: higher revolving-credit use and more recent late payments are both associated with higher model credit-risk estimates across the comparison applications.

Vertical axis: Average model credit-risk estimate across comparison applications (%)

Displayed range: 4 to 24

Use of available revolving credit

Recorded value: 78%

Average model risk generally rises as revolving-credit use increases.

RECORDED VALUE

78 % used → average estimate 16.9%

Recent late payments

Recorded value: 2 late payments

Average model risk generally rises as recent late payments increase.

RECORDED VALUE

2 payments / 12 months → average estimate 14.8%
